Scenario Card 1

1

Savings fade

Each year's saving after the first year of saving is 30% lower than the year before. The first saving, in year 2, stays at the base amount.

All other inputs stay at the base values, which are on the board page.

Change: Savings are 30% lower each year after the first year of saving

Base ratio: 1.86. Write your prediction of the new ratio before you see the results.

Prediction and reason:

What evidence would show whether this change is realistic?

This is a fictional scenario. It does not show how the programme actually performed. Post your card number and prediction above the line. After the results are given out, post your card number and the result below the line.

Scenario Card 2

2

Hidden costs

We add 600 AED per business for administration and business time, at year 0, in addition to the 1,800 AED already included. Check that the costs are not already counted.

All other inputs stay at the base values, which are on the board page.

Change: Add 600 AED of costs at year 0

Base ratio: 1.86. Write your prediction of the new ratio before you see the results.

Prediction and reason:

What evidence would show whether this change is realistic?

This is a fictional scenario. It does not show how the programme actually performed. Post your card number and prediction above the line. After the results are given out, post your card number and the result below the line.

Scenario Card 3

3

A higher discount rate

We use a discount rate of 8% instead of 5%, over the same five years of savings.

All other inputs stay at the base values, which are on the board page.

Change: Discount rate of 8% instead of 5%

Base ratio: 1.86. Write your prediction of the new ratio before you see the results.

Prediction and reason:

What evidence would show whether this change is realistic?

This is a fictional scenario. It does not show how the programme actually performed. Post your card number and prediction above the line. After the results are given out, post your card number and the result below the line.

Scenario Card 4

4

A shorter life

Savings last three years instead of five. Savings are made only in years 2, 3 and 4.

All other inputs stay at the base values, which are on the board page.

Change: Savings last three years (years 2 to 4)

Base ratio: 1.86. Write your prediction of the new ratio before you see the results.

Prediction and reason:

What evidence would show whether this change is realistic?

This is a fictional scenario. It does not show how the programme actually performed. Post your card number and prediction above the line. After the results are given out, post your card number and the result below the line.

Scenario Card 5

5

Savings fade and hidden costs

This card changes two inputs. Each year's saving after the first is 30% lower than the year before, and we add 600 AED at year 0.

All other inputs stay at the base values, which are on the board page.

Change: Savings fade by 30% a year and add 600 AED at year 0

Base ratio: 1.86. Write your prediction of the new ratio before you see the results.

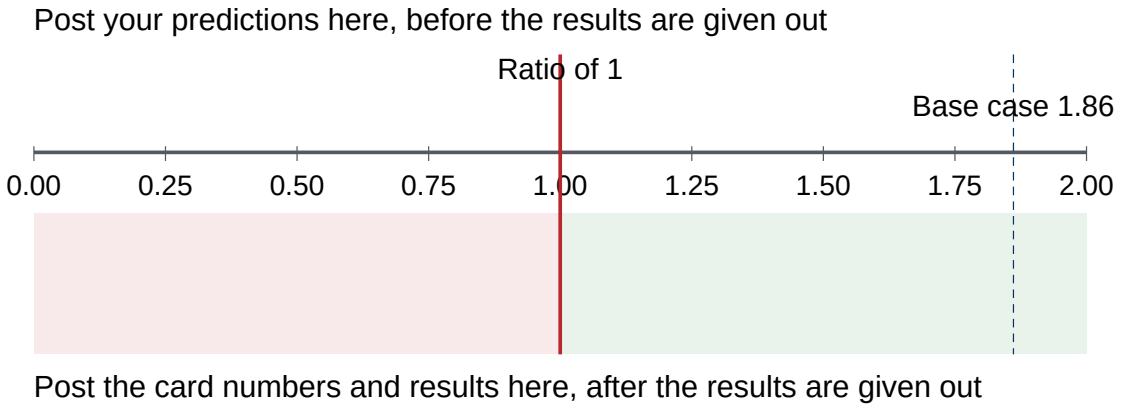
Prediction and reason:

What evidence would show whether this change is realistic?

This is a fictional scenario. It does not show how the programme actually performed. Post your card number and prediction above the line. After the results are given out, post your card number and the result below the line.

Page 6 | Two-lane board for the benefit-cost ratio

Post your predictions above the line before the results. After the results are given out, post the card numbers and the results below the line.



The base case is a benefit-cost ratio of 1.86, using the base inputs: annual saving 812 AED, equipment delivery cost 1,800 AED at year 0, no saving in year 1, savings in years 2 to 6, and a discount rate of 5%.

A ratio of 1 is the break-even point: the benefits at value today equal the costs. A result below 1 is conditional on the scenario. It does not show that the programme failed.
