Page 1 | Corrected findings: comparison and uncertainty

GreenWaste is a fictional training case. The outcome is recorded annual waste cost in AED per business at 12 months.

Source index

Anchor	Read it for
F1.1-F1.2	Pilot comparison, interval and district reach
F2.1-F2.2 / T11	City comparisons, requirements and shared data
F3.1-F3.2	Model inputs, cost boundary and sensitivity
F4.1-F4.2	Missing evidence and decision consequence

F1 | Pilot comparison, uncertainty and reach

F1.1. In a separate pilot district, 400 businesses with scores at or below 58 entered a lottery: 200 were assigned to join and 200 to wait. The analysis compares recorded annual waste costs in AED per business at 12 months. Lottery assignment reduces systematic starting selection; credible outcome follow-up still matters. This result describes one district, not national delivery.

F1.2. Estimated annual saving is 1,014 AED per business, with a 95% interval of 862 to 1,167 AED. The interval lies above zero but spans the authority's 1,000 AED minimum-saving rule. The point estimate exceeds that rule; the interval does not settle it. Do not describe uncertainty about the minimum as no evidence of a reduction.

F2 | City comparisons and causal requirements

F2.1. The city has 10,000 businesses: 4,794 participant businesses and 5,206 comparison businesses. Participation is at or below score 58. The difference between the two changes is the participant businesses' change minus the comparison businesses' change: estimated saving 812 AED, interval 792 to 833, below our rule of at least a 1,000 AED reduction. A causal reading requires parallel changes without support; one before measure cannot show earlier trends. Participants' descriptive mean fall of 669 AED is a different comparison and does not by itself establish cause.

F2.2. The fitted score-58 jump uses 545 businesses within two score points and is local. Continuity without support and absence of relevant sorting/other jumps matter. A separate five-point diagnostic shows managers about 5.3 years younger below the cut-off. Matching uses four recorded features; 585 controls are reused, one 440 times, with a 3.0-year mean age gap remaining. Comparability and unmeasured selection remain concerns. The city methods share records; they are not independent replications.

Table T11 | Estimated annual saving per business, AED

Method	Estimated saving AED	95% interval for saving AED
Pilot lottery	1,014	862 to 1,167
City extra change	812	792 to 833
Jump near score 58	721	498 to 943
City matched comparison	1,029	859 to 1,200

Positive saving scale; sorted 95% limits. Each interval is a 95% interval for that method. Matching uncertainty treats the chosen matches as given. Read each row with its population/comparison and requirements, not as a vote.

Page 2 | Corrected findings: spending and next evidence

F3 | Conditional economic model

F3.1. The limited model provisionally uses the city difference-in-differences saving of 812 AED. It assumes 1,800 AED one-off cost at year 0, no benefit in year 1, five equal saving years in years 2-6 and a 5% discount rate. The benefit-cost ratio is 1.86. Costs, timing and persistence are fictional assumptions, not measured programme facts. The benefit still needs a credible causal interpretation.

F3.2. A ratio above 1 compares modelled benefits with included costs; it is not the 1,000 AED annual-saving test. The boundary mixes actors and is not a complete government-budget or social appraisal. Under the previously tested combination of 30% annual benefit decay and 600 AED additional year-0 costs, the ratio is 0.80. Request full cost amounts, timing, perspective and persistence evidence before relying on a national spending conclusion.

F4 | Missing evidence and decision-changing requests

F4.1. Complete generated records in this synthetic training file do not establish real recruitment, measurement reliability or follow-up. No fieldwork/attrition records, earlier city series, score-manipulation audit or complete matching-support assessment are supplied. Do not invent those checks or treat missing evidence as proof that the programme failed.

F4.2. National expansion needs a comparison of the intended population and delivery conditions with the studied setting. Its eligible business count and full budget are not given. Choose the evidence most relevant to your action: target-population/delivery comparison, full costs/persistence, earlier trends/concurrent changes, fieldwork/follow-up, or cut-off/matching credibility. Explain what a favourable or unfavourable answer would change.

D11 | The director’s hypothetical decision

D11. Hypothetical decision: should the director authorise national rollout to businesses scoring at or below 58, and commit a proposed 1,800 AED delivery allowance per business? A limited next phase or deferral is also possible; specify the scale and condition you recommend. The allowance is a planning proposal, not a measured cost. The national eligible count, total budget, full delivery costs and acceptable risk of falling below 1,000 AED annual saving are not supplied.

Drafting requirement

Write connected prose of **at most 150 words**, including finding, action/condition, important limit and next evidence/purpose. Put **source references on a separate line outside the word limit**.

Count whitespace-separated words in the brief body, including headings/labels if you use them there. A correct word count or matching number does not establish faithful interpretation. Different bounded actions can be defensible.

F1-F4 are the drafting evidence. D11 is a hypothetical decision scenario, not an empirical finding or a verified budget. The proposed 1,800 AED allowance does not establish full cost or total national spending.
